Green-red emitting Zn$_2$SiO$_4$:Mn$^{2+}$ phosphor were synthesized at higher sintering temperature and with heavy doping concentrations than a conventional green-emission Zn$_2$SiO$_4$:Mn$^{2+}$ phosphor. The green-red phosphor shows gamma-phase structure and strong photoluminescence intensity under excitation with near-UV light and blue light. The structure, luminescence, and thermal stability of the phosphor are characterized. This phosphor has a potential use for color conversion in white-light-emitting diode.
