Silver antimony sulfide (Ag$_3$SbS$_3$), a p-type semiconductor (SC) material has been synthesized in a solid state route with silver, antimony and sulfur powder precursors in a high temperature oven by gradually increasing the temperature. The product was characterized by powder X-ray diffraction (XRD). Ag$_3$SbS$_3$ has a small band gap ($E_g$) of 2.0 eV and is suitable to absorb solar energy and produce electron-hole (e$^-$-h$^+$) pair which are good candidates for water splitting. Photoelectrochemical study was carried out making films on fluorine-doped tin oxide (FTO) substrate. The preliminary results from photoelectrochemistry and characterization will be presented.
